SESSION 21

Excel & SQL Server with Power Query

Q-1: Connect Excel to SQL Server using Power Query

- Go to Data → Get Data → From Database → From SQL Server Database.
- Enter your server name and database.
- Select the *Restaurants* table (columns: name, cuisine, rating).
- Load it into a new worksheet.

Q-2: Set up a parameterized query in Power Query to filter by cuisine type

- In Excel, create a cell (e.g., B1) where you type the cuisine (e.g., *Chinese*).
- In Power Query, go to Manage Parameters → New Parameter and link it to that cell.
- Modify your SQL query:

```
SELECT name, cuisine, rating
FROM Restaurants
WHERE cuisine = @CuisineParam;
```

Q-3: Enable dynamic refresh

- In Power Query, click Close & Load.
- On the Excel ribbon, go to Data → Refresh All.
- Now, whenever new records are added in SQL Server, click Refresh All to update Excel instantly.

Q-4: Modify Power Query to include only restaurants with rating > 4.0

```
SELECT name, cuisine, rating
FROM Restaurants
WHERE rating > 4.0;
```

- Load results into Excel.
- Insert a Table and add a Bar Chart (Insert → Charts → Bar).
- This creates a dashboard-style view of top-rated restaurants.

Q-5: Parameterized SQL query for rating range (using Copilot guidance)

```
SELECT name, cuisine, rating
FROM Restaurants
WHERE rating BETWEEN @MinRating AND @MaxRating;
```
