Basic SELECT & FROM

Solved Tasks • SQL Code • Easy English Explanations

Learning goal: Use SELECT to choose what data to display, FROM to choose the table, AS to rename output columns, and -- to add a single-line comment.

Task 1 — Display All Columns from restaurants

Question: Run a query to select all columns from a table named restaurants.

```
SELECT * FROM restaurants;
```

Explanation

- `SELECT` tells SQL what data you want to display.
- `*` means all columns in the table.
- `FROM restaurants` tells SQL to read the data from the restaurants table.
- The semicolon `;` marks the end of the SQL statement.

Result: The query displays every column and every row in `restaurants`, such as restaurant ID, name, city, rating, or any other columns actually stored in that table.

Task 2 — Display Only name and rating

Question: Display only the name and rating columns from zomato_reviews.

```
SELECT name, rating
FROM zomato_reviews;
```

Explanation

- `name, rating` lists the two columns to display.
- `FROM zomato_reviews` identifies the source table.
- Because the query names only these two columns, the other columns are not included in the result.

Result: The output has two columns: `name` and `rating`, with rows from `zomato_reviews`.

Task 3 — Rename Output Columns Using AS

Question: Select movie_name and release_year from movies, but display the headings as Title and Year Released.

```
SELECT
    movie_name AS Title,
    release_year AS `Year Released`
FROM movies;
```

Explanation

- `movie_name` selects the movie name column.
- `AS Title` gives that output column the heading `Title`.
- `release_year` selects the release year column.
- `AS` renames the output heading. Backticks around `Year Released` allow the alias to contain a space in MySQL.
- `FROM movies` reads the data from the movies table.

Important: An alias changes the column heading in the query result; it does not rename the actual column stored in the table.

Task 4 — Select All Columns and Add a Comment

Question: Select all columns from products and add a single-line comment explaining the query.

```
-- Display all columns and rows from the products table.
SELECT * FROM products;
```

Explanation

- `--` starts a single-line comment in MySQL. SQL ignores the comment when executing the query.
- `SELECT *` selects all columns.
- `FROM products` reads the data from the products table.

Result: The comment explains the purpose of the query, and the SQL statement displays all rows and columns from `products`.

Quick Revision

SQL syntax	Purpose
`SELECT * FROM table_name;`	Select all columns from a table.
`SELECT column1, column2 FROM table_name;`	Select only the listed columns.
`column_name AS Alias`	Give the output column a new heading.
`-- comment text`	Add a single-line comment.
`FROM table_name`	Specify which table provides the data.
